ON THE DEGREE GROWTH IN SOME POLYNOMIAL DYNAMICAL SYSTEMS AND NONLINEAR PSEUDORANDOM NUMBER GENERATORS

ALINA OSTAFE AND IGOR E. SHPARLINSKI

Abstract. In this paper we study a class of dynamical systems generated by iterations of multivariate polynomials and estimate the degree growth of these iterations. We use these estimates to bound exponential sums along the orbits of these dynamical systems and show that they admit much stronger estimates than in the general case and thus can be of use for pseudorandom number generation.

1. Introduction

Given a system of $r$ polynomials $\mathcal{F} = \{f_0, \ldots, f_{r-1}\}$ in $r$ variables over a ring $\mathcal{R}$, one can naturally define a dynamical system generated by its iterations:

$$f_i^{(0)} = f_i, \quad f_i^{(k)} = f_i^{(k-1)}(f_0, \ldots, f_{r-1}), \quad k = 0, 1, \ldots,$$

for each $i = 0, \ldots, r - 1$; see [1, 2, 3, 7, 9, 10, 14, 15, 26, 33, 42, 43, 44] and references therein for various aspects of such dynamical systems. It is also natural to consider the orbits obtained by such iterations evaluated at a certain initial value $(u_{k,0}, \ldots, u_{k,r-1})$.

In the special case of one linear univariate polynomial over a residue ring or a finite field, such iterations, known as linear congruential generators, have been successfully used for decades in the theory of quasi-Monte Carlo methods; see [35, 36].

Unfortunately, in cryptographic settings, such linear generators have been successfully attacked [11, 19, 27, 29, 31] and thus deemed unusable for cryptographic purposes. It should be noted that nonlinear generators have also been attacked [4, 5, 21, 24], but the attacks are much weaker and do not rule out their use for cryptographic purposes (provided reasonable precautions are made). Although linear congruential generators have been used quite successfully for quasi-Monte Carlo methods, their linear structure shows in these applications too and often limits their applicability; see [35, 36].

Motivated by these potential applications, the statistical uniformity of the distribution (measured by the discrepancy) of one and multidimensional nonlinear polynomial generators have been studied in [20, 22, 27, 30, 31, 45]. However, all previously known results are nontrivial only for those polynomial generators that produce sequences of extremely large period, which could be hard to achieve in...
practice. The reason behind this is that typically the degree of iterated polynomial systems grows exponentially, and that in all previous results, the saving over the trivial bound has been logarithmic. Furthermore, it is easy to see that in the one-dimensional case (that is, for \( r = 1 \)) the exponential growth of the degree of iterations of a nonlinear polynomial is unavoidable. One also expects the same behaviour in the multidimensional case for “random” polynomials \( f_0, \ldots, f_{r-1} \). However, for some specially selected polynomials \( f_0, \ldots, f_{r-1} \), the degree may grow significantly slower.

Indeed, here we describe a rather wide class of polynomial systems with polynomial growth of the degree of their iterations. As a result we obtain much better estimates of exponential sums, and thus of discrepancy, for vectors generated by these iterations, with a saving over the trivial bound being a power of \( p \). Our construction resembles that of triangular maps of \[33\] but behaves quite differently; for example, triangular maps in \[33\] have the fastest possible degree growth.

We remark that, in the case of the so-called inversive generator, rather strong estimates are also available \[38, 39\], but this generator involves a modular inversion at each step, which is a computationally expensive operation. Another alternative where stronger than general bounds are known is the power generator, which essentially consists of iterating a monomial map \( X \rightarrow X^{e_i} \); see \[8, 16, 17, 34, 46\] and especially the recent result of J. Bourgain \[6\] on the joint distribution of consecutive terms of this generator. Similar results also hold for pseudorandom number generators obtained by iterating Dickson polynomials \[23\] and Redei functions \[25\].

Finally, we note that we also hope that our results may be of use for some applications in polynomial dynamical systems.

2. Polynomial dynamical system with slow degree growth

2.1. Construction. Let \( \mathbb{F} \) be an arbitrary field and let \( \mathcal{F} = \{ f_0, \ldots, f_m \} \) be a system of \( m + 1 \) polynomials in \( \mathbb{F}[X_0, \ldots, X_m] \) defined in the following way:

\[
\begin{align*}
    f_0(X_0, \ldots, X_m) &= X_0 g_0(X_1, \ldots, X_m) + h_0(X_1, \ldots, X_m), \\
    f_1(X_0, \ldots, X_m) &= X_1 g_1(X_2, \ldots, X_m) + h_1(X_2, \ldots, X_m), \\
    &\vdots \\
    f_{m-1}(X_0, \ldots, X_m) &= X_{m-1} g_{m-1}(X_m) + h_{m-1}(X_m), \\
    f_m(X_0, \ldots, X_m) &= aX_m + b,
\end{align*}
\]

where

\[ a, b \in \mathbb{F}, \quad a \neq 0, \quad g_i, h_i \in \mathbb{F}[X_{i+1}, \ldots, X_m], \quad i = 0, \ldots, m - 1. \]

We also impose the condition that each polynomial \( g_i \) has a unique leading monomial \( X_{i+1}^{s_i} \ldots X_m^{s_m} \), that is,

\[
g_i(X_{i+1}, \ldots, X_m) = X_{i+1}^{s_i} \ldots X_m^{s_m} + \tilde{g}_i(X_{i+1}, \ldots, X_m),
\]

where

\[
\deg \tilde{g}_i < \deg g_i = s_{i+1} + \cdots + s_m
\]

and

\[
\deg h_i \leq \deg g_i
\]

for \( i = 0, \ldots, m - 1 \).
For each \(i = 0, \ldots, m\) we define the \(k\)-th iteration of the polynomials \(f_i\) by the recurrence relation
\[
(5) \quad f_i^{(0)} = f_i, \quad f_i^{(k)} = f_i^{(k-1)}(f_0, \ldots, f_m), \quad k = 0, 1, \ldots
\]

2.2. Degree growth. We denote by \(d_{k,i}\) the degree of the polynomial \(f_i^{(k)}\), \(i = 0, \ldots, m\). We also consider the vector of degrees of the iterations
\[
d_k = (d_{k,0}, \ldots, d_{k,m}),
\]
and the upper triangular matrix
\[
S = \begin{pmatrix}
1 & s_{0,1} & s_{0,2} & \cdots & s_{0,m} \\
0 & 1 & s_{1,2} & \cdots & s_{1,m} \\
0 & 0 & 1 & \cdots & 1
\end{pmatrix}
\]
given by the exponents of the leading monomials in \(f_i\), \(i = 0, \ldots, m\). We observe that under iterations we have
\[
f_i^{(k)} = f_i^{(k-1)}g_i(f_{i+1}, \ldots, f_m) + h_i(f_{i+1}, \ldots, f_m),
\]
and using the conditions on the degrees of the polynomials \(g_i\) and \(h_i\) we get
\[
d_{k,i} = d_{k-1,i} + s_{i,i+1}d_{k-1,i+1} + \cdots + s_{i,m}d_{k-1,m}, \quad i = 0, \ldots, m - 1,
d_{k,m} = 1.
\]
Using the above notation, the degrees of the iterations satisfy the relation
\[
d_k = Sd_{k-1}, \quad k \geq 0 \quad \text{and} \quad d_{-1} = (1, \ldots, 1)^t,
\]
which is equivalent to writing
\[
d_k = S^{k+1}(1, \ldots, 1)^t, \quad k \geq 0.
\]

We now show that the degrees of the iterations of \(\mathcal{F}\) grow polynomially.

**Lemma 1.** Let \(f_0, \ldots, f_m \in \mathbb{F}[X_0, \ldots, X_m]\) be as in (1), satisfying the conditions (2), (3) and (4). Then the degrees of the iterations of \(\mathcal{F} = \{f_0, \ldots, f_m\}\) grow as follows:
\[
d_{k,i} = \frac{1}{(m-i)!}k^{m-i}s_{i,i+1} \cdots s_{m-1,m} + \psi_i(k), \quad i = 0, \ldots, m - 1,
d_{k,m} = 1,
\]
where \(\psi_i(T) \in \mathbb{Q}[T]\) is a polynomial of degree \(\deg \psi_i < m - i\).

**Proof.** We use induction on \(m\). For \(m = 1\) one can easily see that we get
\[
d_{k,0} = ks_{0,1} + s_{0,1} + 1 \quad \text{and} \quad d_{k,1} = 1.
\]
We assume the result is true for \(m\) indeterminates. Let \(S\) be the matrix of exponents of the leading monomials in \(\mathcal{F}\) as above. We write \(S\) in the following way:
\[
S = \begin{pmatrix}
R & s \\
0 & 1
\end{pmatrix},
\]
where \(R\) is the matrix given by the exponents of the first \(m\) indeterminates in the leading monomials of \(f_i\), \(i = 0, \ldots, m - 1\), and \(s = (s_{0,m}, \ldots, s_{m-1,m})\). For a vector
It is easy to note that the maximal degree of the \( k \)th induction hypothesis we get \( v \) componentwise, we have
\[
(2) t \quad \text{respectively. We also denote by} \ e \quad \text{the unit vector} \ e = (1, \ldots, 1) ∈ \mathbb{F}^m. \quad \text{Using this notation and recalling (3), we obtain}
\]
\[
d_k = S^{k+1} e^t = \left( R^{k+1} 0 \begin{array}{c} R^k + \cdots + R + I \end{array} s^t \right) e^t.
\]

Componentwise, we have
\[
d_{k,i} = R^{k+1} (e^t)_i + (R^k + \cdots + R + I) s^t_i, \quad i = 0, \ldots, m - 1,
\]
\[
d_{k,m} = 1.
\]

It is easy to note that the maximal degree of the \( k \)th iteration of polynomials \( f_i \) for any \( i \) is given by the last position in each row of \( S^{k+1} \). Using this remark and the induction hypothesis we get
\[
(R^j s^t)_i = \frac{1}{(m - 1 - j)!} j^{m-1-i} s_{i,i+1} \cdots s_{m-2,m-1} s_{m-1,m} + \varphi_i(j),
\]
for some polynomials \( \varphi_i(Z) ∈ \mathbb{Q}[Z] \) of degree \( \deg \varphi_i < m - 1 - i \). Then
\[
\sum_{j=0}^{k} (R^j s^t)_i = \frac{1}{(m - 1 - i)!} s_{i,i+1} \cdots s_{m-1,m} \sum_{j=0}^{k} j^{m-1-i} + \tilde{\varphi}_i(k),
\]
for some polynomials \( \tilde{\varphi}_i(Z) ∈ \mathbb{Q}[Z] \) of degree \( \deg \tilde{\varphi}_i < m - i \). As
\[
\sum_{j=0}^{k} j^{m-1-i} = \frac{1}{m - i} (B_{m-i}(k + 1) - B_{m-i}(0)),
\]
where \( B_{m-i} \) is the Bernoulli polynomial of degree \( m - i \) (which has the leading coefficient equal to 1), we finally obtain the desired result. \( \square \)

**Corollary 2.** Let \( f_0, \ldots, f_m ∈ \mathbb{F}[X_0, \ldots, X_m] \) be as in (1), satisfying the conditions (2), (3) and (4). If \( s_0, s_1, \ldots, s_{m-1,m} \neq 0 \), then for any integer \( ν ≥ 1 \) there is a constant \( k_0 \) depending only on the matrix \( S \) and \( ν \) such that for any integers \( k_1, ℓ_1, \ldots, k_ν, ℓ_ν ≥ k_0 \) and any nonzero \( a = (a_0, \ldots, a_{m-1}) ∈ \mathbb{F}^m \),
\[
F_{a,k_1,ℓ_1,\ldots,k_ν,ℓ_ν} = \sum_{i=0}^{m-1} a_i \sum_{j=1}^{ν} \left( f_i^{(k_j)} - f_i^{(ℓ_j)} \right)
\]
is a nonconstant polynomial of degree
\[
\deg F_{a,k_1,ℓ_1,\ldots,k_ν,ℓ_ν} = O(k^m),
\]
where
\[
k = \max\{k_1, ℓ_1, \ldots, k_ν, ℓ_ν\}
\]
unless the components of the vectors
\[
(k_1, \ldots, k_ν) \quad \text{and} \quad (ℓ_1, \ldots, ℓ_ν)
\]
are permutations of each other.

**Proof.** Let \( i_0 \) be the smallest integer with \( a_{i_0} \neq 0 \). Performing all trivial cancellations, without loss of generality we can also assume that the vectors \( (k_1, \ldots, k_ν) \) and \( (ℓ_1, \ldots, ℓ_ν) \) have no common elements. Thus the largest element amongst them, \( k \), is unique. It is now clear from Lemma (2) that the leading term of \( f_i^{(k)} \) is present in \( F_{a,k_1,ℓ_1,\ldots,k_ν,ℓ_ν} \). \( \square \)
3. POLYNOMIAL PSEUDORANDOM NUMBER GENERATORS

3.1. Construction. Let $\mathcal{F} = \{f_0, \ldots, f_m\}$ be a list of $m+1$ polynomials in $\mathbb{F}_p[X_0, \ldots, X_m]$ defined as in section 2. We consider the sequence defined by a recurrence congruence modulo a prime $p$ of the form

$$u_{n+1,i} \equiv f_i(u_{n,0}, \ldots, u_{n,m}) \pmod{p}, \quad n = 0, 1, \ldots,$$

with some initial values $u_{0,0}, \ldots, u_{0,m}$. We also assume that $0 \leq u_{n,i} < p$, $i = 0, \ldots, m$, $n = 0, 1, \ldots$. Using the following vector notation:

$$w_n = (u_{n,0}, \ldots, u_{n,m}),$$

and

$$\mathcal{F} = (f_0(X_0, \ldots, X_m), \ldots, f_m(X_0, \ldots, X_m)),$$

we have the recurrence relation

$$w_{n+1} = \mathcal{F}(w_n).$$

In particular, for any $n, k \geq 0$ and $i = 0, \ldots, m$ we have

$$u_{n+k,i} = f_i^{(k)}(u_{n,0}, \ldots, u_{n,m})$$

or

$$w_{n+k} = \mathcal{F}^{(k)}(w_n).$$

Clearly the sequence of vectors $w_n$ is eventually periodic with some period $T \leq p^{m+1}$. Without loss of generality we assume that it is

$$w_{n+T} = w_n, \quad n = 0, 1, \ldots.$$
Assume that the sequence \( \{u_n\} \) generated by (7) is purely periodic with an arbitrary period \( T \). For an integer vector \( a = (a_0, \ldots, a_{m-1}) \in \mathbb{Z}^m \) we introduce the exponential sum
\[
S_a(N) = \sum_{n=0}^{N-1} e \left( \sum_{i=0}^{m-1} a_i u_{n,i} \right).
\]

**Theorem 4.** Let the sequence \( \{u_n\} \) be given by (7), where the family of \( m+1 \) polynomials \( F = \{f_0, \ldots, f_m\} \in \mathbb{F}_p[X_0, \ldots, X_m] \) of total degree \( d \geq 2 \) is of the form (1), satisfying the conditions (2), (3) and (4), and such that \( s_{0,1} \ldots s_{m-1,m} \neq 0 \). Assume that \( \{u_n\} \) is purely periodic with period \( T \). Then for any fixed integer \( \nu \geq 1 \), and any positive integer \( N \leq T \), the bound
\[
\max_{\gcd(a_0, \ldots, a_{m-1}, p)=1} |S_a(N)| = O \left( p^{s_{m,\nu}} N^{1-\beta_{m,\nu}} \right)
\]
holds, where
\[
\alpha_{m,\nu} = \frac{2m^2 + 2m\nu + 2m + \nu}{4\nu(m + \nu)} \quad \text{and} \quad \beta_{m,\nu} = \frac{1}{2\nu}
\]
and the implied constant depends only on \( d, m \) and \( \nu \).

**Proof.** Select any \( a = (a_0, \ldots, a_{m-1}) \in \mathbb{Z}^m \) with \( \gcd(a_0, \ldots, a_{m-1}, p) = 1 \). It is obvious that for any integer \( k \geq 1 \) we have
\[
\left| S_a(N) - \sum_{n=0}^{N-1} e \left( \sum_{i=0}^{m-1} a_i u_{n+k,i} \right) \right| \leq 2k.
\]
Let \( k_0 \) be the same as in Corollary 2. Therefore, for any integer \( K \geq k_0 \),
\[
(K - k_0 + 1)|S_a(N)| \leq W + K^2,
\]
where
\[
W = \left| \sum_{n=0}^{N-1} \sum_{k=k_0}^{K} e \left( \sum_{i=0}^{m-1} a_i u_{n+k,i} \right) \right| \leq \sum_{n=0}^{N-1} \sum_{k=k_0}^{K} e \left( \sum_{i=0}^{m-1} a_i u_{n+k,i} \right).
\]

As before, we define the sequence of polynomials
\[
f_i^{(k)}(X_0, \ldots, X_m) \in \mathbb{F}_p[X_0, \ldots, X_m]
\]
by (5). Then
\[
W^{2\nu} \leq N^{2\nu-1} \sum_{n=0}^{N-1} \left| \sum_{k=k_0}^{K} e \left( \sum_{i=0}^{m-1} a_i f_i^{(k)}(u_n) \right) \right|^{2\nu}
\]
\[
\leq N^{2\nu-1} \sum_{w_0, \ldots, w_m \in \mathbb{F}_p} \left| \sum_{k=k_0}^{K} e \left( \sum_{i=0}^{m-1} a_i f_i^{(k)}(w_0, \ldots, w_m) \right) \right|^{2\nu}
\]
\[
= N^{2\nu-1} \sum_{k_1, \ell_1, \ldots, k_\nu, \ell_\nu = k_0} \sum_{w \in \mathbb{F}_p^{m+1}} e \left( \sum_{i=0}^{m-1} a_i \sum_{j=1}^{\nu} \left( f_i^{(k_j)}(w) - f_i^{(\ell_j)}(w) \right) \right).
\]

For \( O(K^\nu) \) vectors
\( (k_1, \ldots, k_\nu) \) and \( (\ell_1, \ldots, \ell_\nu) \), which are permutations of each other, we estimate the inner sum trivially as \( p^{m+1} \).
For the other $O(K^{2\nu})$ vectors, we combine Corollary 2 with Lemma 3 getting the upper bound $K^m p^{m+1/2}$ for the inner sum for at most $K^2$ sums. Hence,

\[ W^{2\nu} \leq K^\nu N^{2\nu-1} p^{m+1} + K^{m+2\nu} N^{2\nu-1} p^{m+1/2}. \]

Inserting this bound in (8), we derive

\[ S_a(N) = O \left( K^{-1/2} N^{1-1/2\nu} p^{(m+1)/2\nu} + K^{m/2\nu} N^{1-1/2\nu} p^{(2m+1)/4\nu} + K \right). \]

Choosing $K = \lceil p^{1/2(m+\nu)} \rceil$ (and assuming that $p$ is large enough, so $K \geq k_0$), after simple calculations we obtain the desired result. □

Since

\[ \lim_{\nu \to \infty} \alpha_{m,\nu}/\beta_{m,\nu} = m + 1/2, \]

we see from Theorem 4 that for any fixed $\varepsilon > 0$ there is a $\delta > 0$ such that if $T \geq N \geq p^{m+1/2+\varepsilon}$, then

\[ \max_{\gcd(a_0, \ldots, a_{m-1}, p) = 1} |S_a(N)| = O \left( N^{1-\delta} \right) \]

(to see this, it is enough to choose a sufficiently large $\nu$). On the other hand, when $T$ and $N$ are close to their largest possible value $p^{m+1}$, that is, if

\[ T \geq N \geq p^{m+1+o(1)}, \]

then Theorem 4 applied with $\nu = 1$ gives the estimate

\[ \max_{\gcd(a_0, \ldots, a_{m-1}, p) = 1} |S_a(N)| \leq N^{1-1/4(m+1)^2+o(1)}. \]

3.3. Discrepancy. Given a sequence $\Gamma$ of $N$ points,

\[ \Gamma = \{ (\gamma_{n,0}, \ldots, \gamma_{n,m-1})_{n=0}^{N-1} \} \]

in the $m$-dimensional unit cube $[0,1)^m$, it is natural to measure the level of its statistical uniformity in terms of the discrepancy $\Delta(\Gamma)$. More precisely,

\[ \Delta(\Gamma) = \sup_{B \subseteq [0,1)^m} \left| \frac{T_{\Gamma}(B)}{N} - |B| \right|, \]

where $T_{\Gamma}(B)$ is the number of points of $\Gamma$ inside the box

\[ B = [a_1, \beta_1] \times \ldots \times [a_m, \beta_m] \subseteq [0,1)^m \]

and the supremum is taken over all such boxes; see [13, 30].

We recall that the discrepancy is a widely accepted quantitative measure of uniformity of distribution of sequences, and thus good pseudorandom sequences should (after an appropriate scaling) have a small discrepancy; see [35, 36].

Typically the bounds on the discrepancy of a sequence are derived from bounds of exponential sums with elements of this sequence. The relation is made explicit in the celebrated Koksma–Szüsz inequality, see [13, Theorem 1.21], which we present in the following form.
Lemma 5. For any integer \( L > 1 \) and any sequence \( \Gamma \) of \( N \) points the discrepancy \( \Delta(\Gamma) \) satisfies the following bound:

\[
\Delta(\Gamma) \leq O\left( \frac{1}{L} + \frac{1}{N} \sum_{|a_0|, \ldots, |a_{m-1}| \leq L} \prod_{j=0}^{m-1} \frac{1}{|a_j|+1} \sum_{n=0}^{N-1} \exp \left( 2\pi i \sum_{j=0}^{m-1} a_j^n \gamma_j, n \right) \right)
\]

Now, combining Lemma 5 with the bound obtained in Theorem 4 and taking \( L = p - 1 \), we obtain:

Theorem 6. Let the sequence \( \{u_n\} \) be given by (7), where the family of \( m+1 \) polynomials \( F = \{f_0, \ldots, f_m\} \in \mathbb{F}_p[X_0, \ldots, X_m] \) of total degree \( d \geq 2 \) is of the form (1), satisfying the conditions (2), (3) and (4), and such that \( s_{0,1}, \ldots, s_{m-1,m} \neq 0 \). Assume that \( \{u_n\} \) is purely periodic with period \( T \). Then for any fixed integer \( \nu \geq 1 \), and any positive integer \( N \leq T \), the discrepancy \( D_N \) of the sequence \( \left( \frac{u_{n,0}}{p}, \ldots, \frac{u_{n,m-1}}{p} \right) \), \( n = 0, \ldots, N-1 \), satisfies the bound

\[
D_N = O \left( p^{\alpha_{m,\nu}} N^{-\beta_{m,\nu}} (\log p)^m \right),
\]

where

\[
\alpha_{m,\nu} = \frac{2m^2 + 2m\nu + 2m + \nu}{4\nu(m + \nu)} \quad \text{and} \quad \beta_{m,\nu} = \frac{1}{2\nu}
\]

and the implied constant depends only on \( d, m \) and \( \nu \).

We remark that the same comments at the end of Section 3.2 also apply to Theorem 6.

4. Remarks and open questions

We recall that the dynamical degree \( \text{dyndeg} F \) of the polynomial system \( F \) and of the associated affine map \( F : \mathbb{F}^r \to \mathbb{F}^r \) is defined as

\[
\text{dyndeg} F = \lim_{k \to \infty} \left( \deg F^{(k)} \right)^{1/k},
\]

where \( F^{(k)} \) is the \( k \)th iteration of \( F \) (and \( \deg F^{(k)} \) is the largest degree of its components); see [43, Section 7.1.3]. We note that the polynomial systems \( F \) which we have constructed in (1) satisfy \( \text{dyndeg} F = 1 \) under the conditions (2), (3) and (4). Furthermore, for any nonlinear polynomial system \( F \) with \( \text{dyndeg} F = 1 \), one can obtain an improvement of the generic bounds on the corresponding exponential sums and the discrepancy of the generated sequences. However the actual improvement depends on the speed of the convergence.

One of the attractive choices of polynomials (1), which leads to a very fast pseudorandom number generator, is

\[
g_i(X_{i+1}, \ldots, X_m) = X_{i+1} \quad \text{and} \quad h_i(X_{i+1}, \ldots, X_m) = a_i
\]

for some constants \( a_i \in \mathbb{F}_p, i = 0, \ldots, m-1 \). The corresponding sequence of vectors is generated at the cost of one multiplication per component. This naturally leads to a question of studying the periods of such sequences generated by such polynomial dynamical systems.
We also note that it is natural to consider the joint distribution of several con-
secutive vectors

\[(u_n, \ldots, u_{n+s-1}), \quad n = 0, 1, \ldots,\]

in the \(sm\)-dimensional space. It seems that our method (with some minor adjust-
mements) can be applied to derive an appropriate variant of Corollary 2 which is
needed for such a result.

One of the possible ways to improve our results is to construct special polyno-
mials \(F = \{f_0, \ldots, f_{r-1}\}\) such that linear combinations of their iterations, of the
type which appear in the proof of Theorem 3 satisfy the condition of the Deligne
bound 12, that is, have a nonsingular highest form. In fact, even some partial
control over the dimension of the singularity locus of this highest form may already
lead to better estimates via results of Katz 25.

Finally, obtaining stronger results “on average” over all initial values \(w_0 \in F_p\)
is an interesting and challenging question. It is possible that some of the arguments
of 39 may be applied to this problem.

ACKNOWLEDGEMENT

The authors would like to thank Markus Brodmann, Joachim Rosenthal, Joe
Silverman and Arne Winterhof for valuable comments and providing additional
references.

During the preparation of this paper, A. O. was supported in part by the Swiss
National Science Foundation Grant 121874 and I. S. by the Australian Research
Council Grant DP0556431.
